# Cryptography: theory and practice

## In theory

- ▶ Random Oracle
- ▶ Ideal Cipher
- ▶ Perfect source of randomness

## In practice

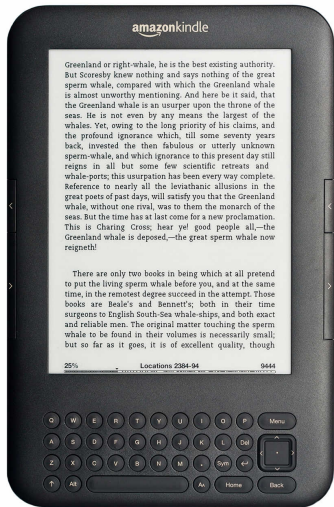

- ▶ Algorithms
  - ▶ AES
  - ▶ SHA-2
  - ▶ RSA
- ▶ Modes of operation
  - ▶ CBC
  - ▶ OAEP
  - ▶ ...
- ▶ Random Number Generators
  - ▶ Hardware RNG
  - ▶ PRNG

## Cryptography in the real world

Several examples of flaws in industrial cryptography:

- ▶ **Bad random source**
  - ▶ SLL with 16-bit entropy (Debian)
  - ▶ ECDSA with fixed  $k$  (Sony)
- ▶ **Bad key size**
  - ▶ RSA-512 (TI)
  - ▶ Export restrictions...
- ▶ **Bad mode of operation**
  - ▶ CBC-MAC with the RC4 stream-cipher (Microsoft)
  - ▶ TEA with Davies-Meyer (Microsoft)
- ▶ **Bad (proprietary) algorithm**
  - ▶ A5/1 (GSM)
  - ▶ Crypto-1 (MIFARE/NXP)
  - ▶ CSS (DVD forum)
  - ▶ KeeLoq (Microchip)

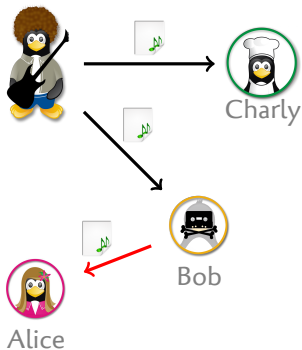

## Amazon Kindle

- ▶ E-book reader by Amazon
- ▶ Most popular e-book reader ( $\approx 50\%$  share)
- ▶ 4 generations, 7 devices
- ▶ Software reader for 7 OS, plus *cloud* reader
- ▶ Several **million devices** sold
- ▶ Amazon sells more e-books than paper books
- ▶ Uses **crypto** for DRM (Digital Rights Management)

# Digital Rights Management

- ▶ Company **sells media**  
(music, video, ebook, game, ...)
- ▶ Wants to **prevent sharing**
  - ▶ Customer should read but not copy

## DRM scheme

- ▶ Encipher media
- ▶ Give player to users
  - ▶ Hardware or software
- ▶ Player contains the key

# Digital Rights Management

- ▶ Company **sells media**  
(music, video, ebook, game, ...)
- ▶ Wants to **prevent sharing**
  - ▶ Customer should read but not copy

## DRM scheme

- ▶ Encipher media
- ▶ Give player to users
  - ▶ Hardware or software
- ▶ Player contains the key

## Breaking DRM

- ▶ Copy the media **while being played**

- ▶ **Extract the key** from the player, decipher media

Tamper-proof hardware? Obfuscation? White-box crypto?

- ▶ **No need to break the crypto!**
- ▶ Pirates break once, copy...

# Digital Rights Management

## Legal User

- ▶ Can only use authorized player
  - ▶ Collection locked-in
- ▶ DRM can restrict user rights
  - ▶ Lending, reselling, ...
- ▶ **No format shifting:**
  - ▶ play DVD on tablet
  - ▶ read ebook w/ speech synth.

## Illegal User

- ▶ Can still find illegal copies
- ▶ Can do anything with the media

## DRM on the Kindle

- ▶ Kindle e-books use DRM
- ▶ Like any DRM system, it is bound to fail
- ▶ In practice, it is **easy to extract the key** (Google for details...)

### Overview

- ▶ In this talk, we study the **cipher** used in this DRM system  
*We don't study the DRM system itself*
- ▶ The DRM system uses a cipher called PC1
- ▶ It's a really **weak cipher**...

# The PC1 Cipher

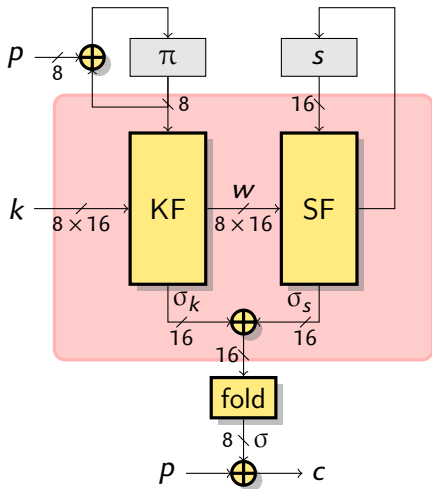

- ▶ Designed by **Pukall in 1991**
- ▶ Posted on Usenet
- ▶ Kindle DRM based on PC1
- ▶ **Self-synchronizing** stream cipher  
*No IV!*
- ▶ **16-bit arithmetic**: add, mult, xor

## Main loop (KF and SF)

```

for 0 ≤ i < 8 do
  w ← w ⊕ ki ⊕ (π × 257)
  x ← 346 × w
  w ← 20021 × w + 1
  s ← s + x
  σ ← σ ⊕ w ⊕ s
  s ← 20021 × (s + (i+1 mod 8)) + x
  
```

## Weakness 1: T-functions

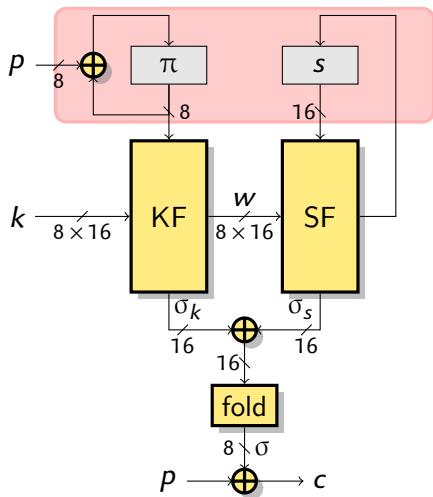

### Weakness

#### This is a T-function

- ▶ Low bits of the output depend only on the low bits of the input
- ▶ Add, mult, xor
- ▶ Guess  $8 \times 9$  bits of the key
- ▶ Get 9 bits before the fold
- ▶ Get 1 bit after the fold
- ▶ Verify with known plaintext
- ▶ **Complexity:**  $2^{72}$   
some bytes of known plaintext

## Weakness 2: small state

### Weakness

The state is very small

$s$  16-bit

$\pi$  8-bit, key-independent

- ▶ Build a set of plaintexts  $x_i || y$ ,  $x_i$ 's with fixed xor-sum
- ▶ With high probability the state collides after  $x_i$  and  $x_j$
- ▶ Same encryption of  $y$
- ▶ **Complexity:**  $2^8$  CP (distinguisher)

## Collision detection

Can we use **state collisions** in a **known-plaintext** attack?

How much wood could a woodchuck chuck

if a woodchuck could chuck wood?  
*ghxadiaphjjxiciwpidkasqghugbqsjbf*

- ▶ In a natural language text, some words will be **repeated**.
- ▶ With some probability ( $p \approx 2^{-24}$ ), two instances of a repeated word begin with the **same state**.
- ▶ This gives a **repetition in the ciphertext**.
- ▶ When we detect a repetition in the plaintext and ciphertext, we can assume that the **state is colliding**.

## Collision Based Key-recovery

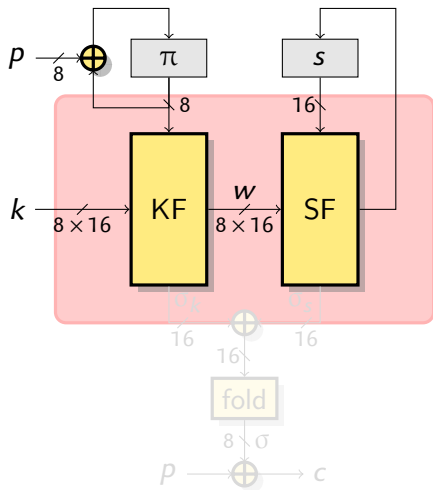

- ▶ Use state collisions to test key guess
- ▶ Skip output part

### Weakness

This is a T-function

- ▶ Guess  $8 \times 1$  bits of the key
- ▶ Compute 1 bit of  $s$ , check collisions in  $s$
- ▶ Repeat with 2<sup>nd</sup> bit, ...

- ▶ Repeat with 2<sup>nd</sup> bit, ...

## Improving the Complexity

- ▶ Simplified state update:

$$s^{t+1} = \bar{w}^t + b \times s^t + c$$

- ▶  $\bar{w} \triangleq \sum_{i=0}^7 (a_i \times w_i)$
- ▶ key-dep. S-box  $KF' : \pi \rightarrow \bar{w}_\pi$

- ▶ Iterate the state update:

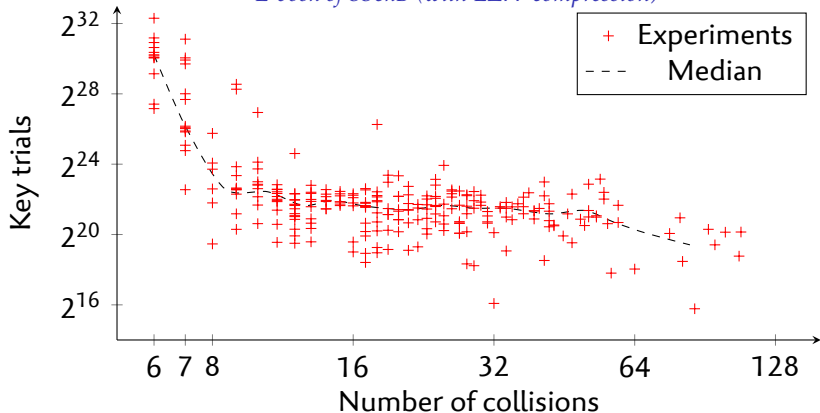

$$s^t = R^t(\bar{w}_0, \dots, \bar{w}_{255}) \text{ linear}$$

Explicit with known  $\pi^t$

- ▶ State collisions give **linear relations** of  $\bar{w}_x$ :  $R^t = R^u$ 
  - ▶ Look for sparse relations
- ▶ For each (partial) key guess, **compute  $\bar{w}_x$  & check relations**
  - ▶ Faster than computing  $s$

# Experiments

*E-book of 336kB (with LZ77 compression)*

## Practical key-recovery attack

Complexity  $\approx 2^{31}$  with  $\approx 2^{20}$  bytes of (low entropy) known plaintext  
Key trial costs less than 256 instead of full encryption

## Ciphertext Only Attack

### Main idea

If the state  $(s, \pi)$  collides, then the output stream  $\sigma$  is the same.

Note that  $s$  depend on the key, but  $\pi = \bigoplus p^i$

Consider two positions  $t, u$  and a random key:

$$\Pr_{\mathcal{K}}[\sigma^t = \sigma^u] \approx \begin{cases} 2^{-8} & \text{if } \pi^t \neq \pi^u \\ 2^{-8} + \Pr[s^t = s^u] & \text{if } \pi^t = \pi^u \end{cases}$$

$$c^t \oplus c^u = \sigma^t \oplus p^t \oplus \sigma^u \oplus p^u$$

- ▶ Consider **several copies** of a given text, encrypted with different, **unrelated keys** (collusion).
- ▶ Look at the distribution of  $c^t \oplus c^u$ :
  - ▶ If flat,  $\pi^t \neq \pi^u$
  - ▶ If **one peak**, then  $\pi^t = \pi^u$ , and get  $p^t \oplus p^u$

## Ciphertext Only Attack

Note that  $s$  depend on the key, but  $\pi = \bigoplus p^i$

Consider two positions  $t, u$  and a random key:

$$\Pr_{\mathcal{K}} [c^t \oplus c^u = X] \approx \begin{cases} 2^{-8} & \text{if } \pi^t \neq \pi^u \\ 2^{-8} + \Pr [s^t = s^{t'}] & \text{if } \pi^t = \pi^u, X = p^t \oplus p^u \end{cases}$$

$$c^t \oplus c^u = \sigma^t \oplus p^t \oplus \sigma^u \oplus p^u$$

- ▶ Consider **several copies** of a given text, encrypted with different, **unrelated keys** (collusion).

  - ▶ If **one peak**, then  $\pi^t = \pi^u$ , and get  $p^t \oplus p^u$

## Tricks to Improve the Bias

- 1 There are similar bias with the low bits of  $\sigma$ :

Use bias in **low bit** of  $c^t \oplus c^u$ : if  $\pi^t = \pi^u$  and  $X \equiv p^t \oplus p^u \pmod{2}$ , then

$$\Pr_K [c^t \oplus c^u \equiv X \pmod{2}] \approx 2^{-1} + \Pr [s^t \equiv s^u \pmod{2^9}]$$

- 2 Use positions with  $t \equiv u \pmod{8}$

▶ This gives a bias of  $2^{-6}$  to  $2^{-4}$  (cancellations in the state update)

# Clustering algorithm

## Finding relations

- ▶ Look at the distribution of  $c^t \oplus c^u \bmod 2$ :
  - ▶ If flat, then  $\pi^t \neq \pi^u$
  - ▶ If **one peak**, then  $\pi^t = \pi^u$
- ▶ Use a **clustering algorithm** to recover  $\pi^t$ :
  - ▶ Initially, all positions are assigned a different *color*.
  - ▶ When  $\pi^t = \pi^u$  is detected, merge colors.
- ▶ Easier to detect bias with larger clusters
  - ▶ Combine the biases  $c^{t_i} \oplus c^{t_j}$
- ▶ At the end, 256 colors correspond to the 256 values of  $\pi^t$ 
  - ▶ Recover the value of  $\pi^t$  using some known plaintext.
  - ▶ Recover  $p$ .
- ▶ **Practical with  $2^{10}$  keys, and  $2^{17}$  data**

## Conclusion

*Don't use an untested cipher!*

Attacks on PC1		Complexity	Data	Ref.
Dist.	Chosen plaintext	$2^{16}$	$2^{16}$	Usenet
Key rec.	Known plaintext	$2^{72}$	$2^4$	Usenet
Key rec.	Known plaintext	$2^{31}$	$2^{20}$	New
Key rec.	Ciphertext only, $2^{10}$ unrelated keys	$2^{35}$	$2^{17}$ per key	New
Attacks on PSCHF		Complexity		Ref.
$2^{\text{nd}}$ pre.	with meaningful messages	$2^{24}$		New

*Impact for the Kindle?*

Pirates can **just extract the key...**

*They don't need to break the cipher to break the DRM scheme.*
