# Hash Functions

In what follows,  $\mathbb{F}_q$  is the finite field with  $q$  elements.

## Definition

Here, a hash function  $H$  maps tuples of elements of  $\mathbb{F}_q$  to  $\mathbb{F}_q^d$ , for some fixed  $d$ .

# Hash Functions

In what follows,  $\mathbb{F}_q$  is the finite field with  $q$  elements.

## Definition

Here, a hash function  $H$  maps tuples of elements of  $\mathbb{F}_q$  to  $\mathbb{F}_q^d$ , for some fixed  $d$ .

**Collision resistance:** it must be **infeasible in practice** to find tuples  $x$  and  $y$  such that  $H(x) = H(y)$ .

**Oneway-ness:** given  $y \in (\mathbb{F}_q)^d$ , it must be **infeasible in practice** to find  $x$  such that  $H(x) = y$ .

## A Natural Question

What are the differences between the “**binary world**” and the  
“**arithmetization-oriented**” world?

## A Mismatch in Domain

For SHA-X, we have

- $q = 2$
- $160 \leq d \leq 512$
- at least 10 years old
- Based on logical gates/CPU instructions

For arithmetization-oriented functions:

- $q \in \{2^n, p\}$ , where  $p \geq 2^n, n \geq 64$
- $2 \leq d \leq 4$
- at most 5 years old
- Based on finite field arithmetic

## A Mismatch in Domain

For SHA-X, we have

- $q = 2$
- $160 \leq d \leq 512$
- at least 10 years old
- Based on logical gates/CPU instructions

For arithmetization-oriented functions:

- $q \in \{2^n, p\}$ , where  $p \geq 2^n, n \geq 64$
- $2 \leq d \leq 4$
- at most 5 years old
- Based on finite field arithmetic

## A Mismatch in Domain

For SHA-X, we have

- $q = 2$
- $160 \leq d \leq 512$
- at least 10 years old
- Based on logical gates/CPU instructions

For arithmetization-oriented functions:

- $q \in \{2^n, p\}$ , where  $p \geq 2^n, n \geq 64$
- $2 \leq d \leq 4$
- at most 5 years old
- Based on finite field arithmetic

## A (Smaller) Mismatch in Properties

### Binary Hash Functions

The sub-components must provide:

**Security:** well-known attacks should not work

**Operations:**  $y \leftarrow R(x)$  must be fast/time constant

**Efficiency:** easy implementation in software/hardware

## A (Smaller) Mismatch in Properties

### Binary Hash Functions

The sub-components must provide:

**Security:** well-known attacks should not work

**Operations:**  $y \leftarrow R(x)$  must be fast/time constant

**Efficiency:** easy implementation in software/hardware

### Arithmetization-oriented Hash Functions

The sub-components must provide:

**Security:** well-known attacks should not work

**Operations:** verifying that  $y = R(x)$  must be efficient

**Efficiency:** easy integration without advanced protocols

## A (Smaller) Mismatch in Properties

### Binary Hash Functions

The sub-components must provide:

**Security:** well-known attacks should not work

**Operations:**  $y \leftarrow R(x)$  must be fast/time constant

**Efficiency:** easy implementation in software/hardware

### Arithmetization-oriented Hash Functions

The sub-components must provide:

**Security:** well-known attacks should not work

**Operations:** verifying that  $y = R(x)$  must be efficient

**Efficiency:** easy integration without advanced protocols

A key difference: **indirect computation**

$$y \leftarrow R(x) \quad \text{vs.} \quad y == R(x)?$$

## Take Away

Arithmetization-oriented  
functions differ **substantially**  
from “classical ones”!

## Plan of this Section

- 1 What are Arithmetization-Oriented Hash Functions
  - Scope statement
  - How do we build and select symmetric primitives?
  - Examples of such Functions
- 2 How Do We Test Their Security?
- 3 Some Cryptanalyses
- 4 Conclusion

## To Build a Hash Function (Sponge Structure)

Modern hash functions usually have a  
**sponge structure**

## To Build a Hash Function (Sponge Structure)

Modern hash functions usually have a  
**sponge structure**

image source: <https://www.iacr.org/authors/tikz/>

### Parameters:

- A rate  $r > 0$  ( $\approx$  throughput)
- A capacity  $c > 0$  ( $\approx$  security level)
- A public permutation  $f$  of  $\mathbb{F}_q^r \times \mathbb{F}_q^c$ .

### Algorithm:

- 1 Turn the message into  $(m_0, \dots, m_{\ell-1})$ , where  $m_i \in \mathbb{F}_q^r$
- 2 Initialize  $(x, y) \in \mathbb{F}_q^r \times \mathbb{F}_q^c$
- 3 For  $i \in \{0, \dots, \ell - 1\}$ :  
 $x \leftarrow x + m_i$   
 $(x, y) \leftarrow f(x, y)$
- 4 Return  $x$

## To Build a Hash Function (Round Function)

The main task is to build the permutation  $f : X \mapsto Y$ . **How** do we do this?

A round function  $F_i$  is iterated multiple times.

It is parameterized by the round number  $i$ .

## To Build a Hash Function (Round Function)

The main task is to build the permutation  $f : X \mapsto Y$ . **How** do we do this?

A round function  $F_i$  is iterated multiple times.  
It is parameterized by the round number  $i$ .

### How to build $F_i$ ?

The description of  $F_i$  is what really differentiates  
hash functions from one another.  
(will be extensively discussed later)

## To Build a Hash Function (Round Function)

The main task is to build the permutation  $f : X \mapsto Y$ . **How** do we do this?

A round function  $F_i$  is iterated multiple times.  
It is parameterized by the round number  $i$ .

### How to build $F_i$ ?

The description of  $F_i$  is what really differentiates  
hash functions from one another.  
(will be extensively discussed later)

### How to choose the number $r$ of rounds?

How many do we need to be safe from all **known**  
attacks, with some **margin**?  
(a deep topic!)

## Next step

OK, I have designed a round function  $F$ , chosen a number  $\ell$  of rounds...

## Next step

OK, I have designed a round function  $F$ , chosen a number  $\ell$  of rounds...

Will people use my algorithm now?

## Next step

OK, I have designed a round function  $F$ , chosen a number  $\ell$  of rounds...

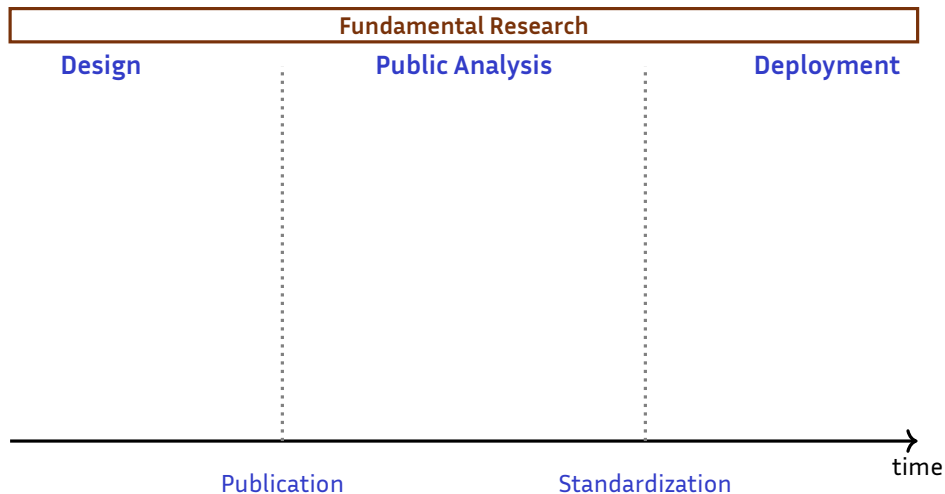

Will people use my algorithm now?

... No.

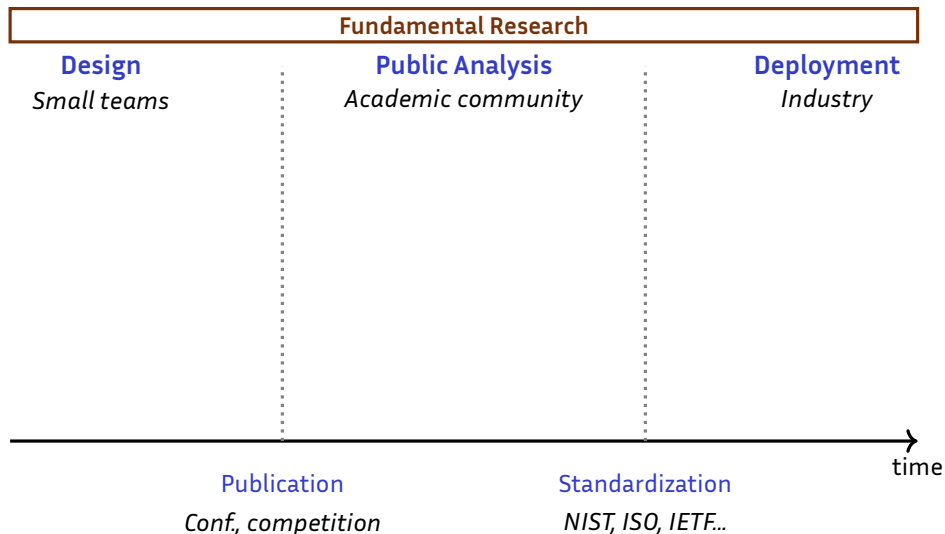

# Cryptographic Pipeline

**Fundamental Research**

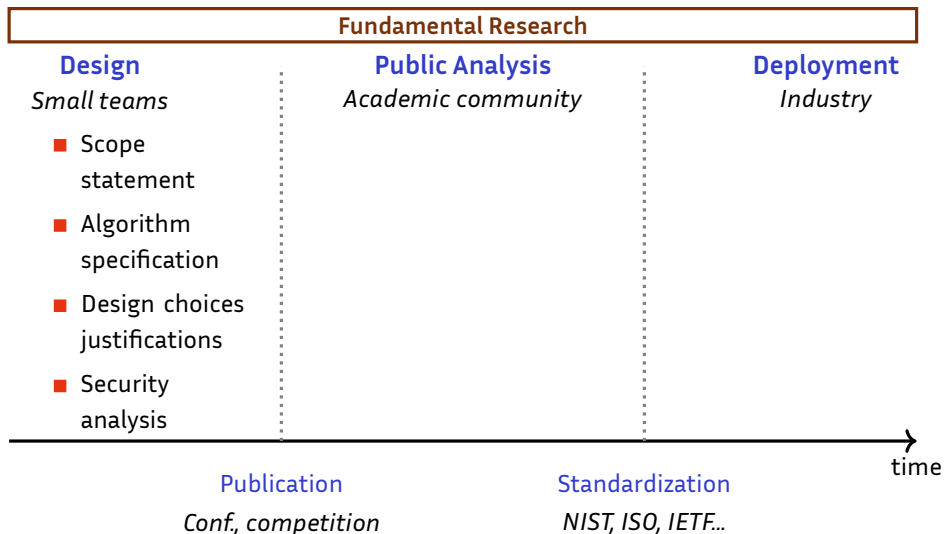

## Cryptographic Pipeline

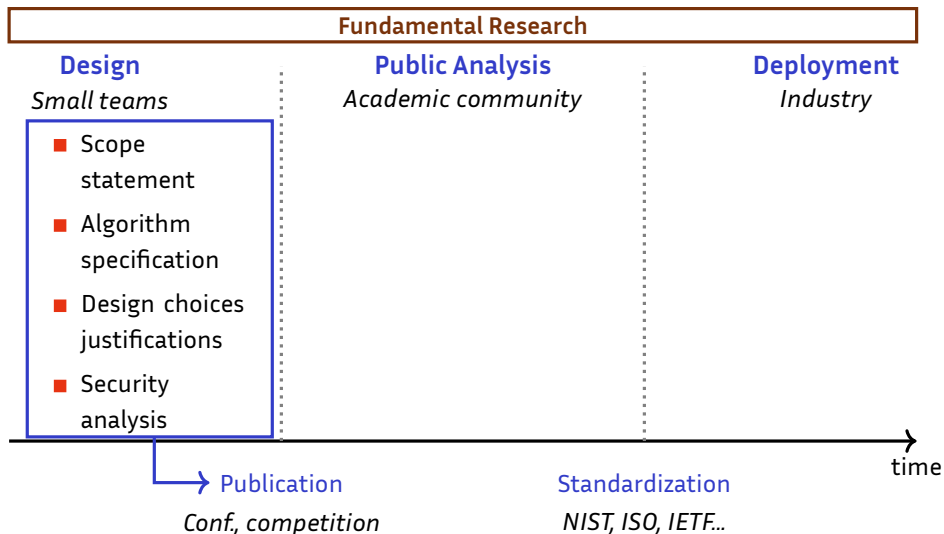

## Cryptographic Pipeline

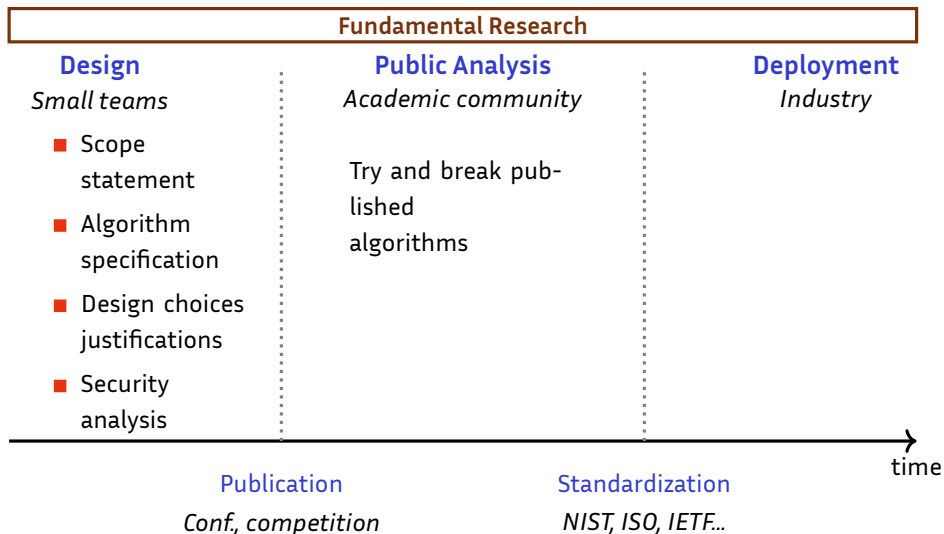

## Cryptographic Pipeline

## Cryptographic Pipeline

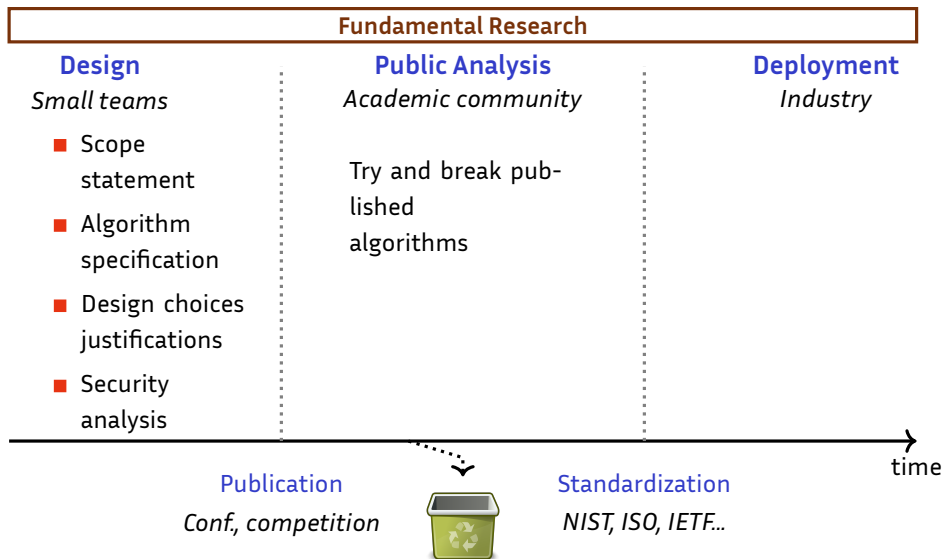

## Cryptographic Pipeline

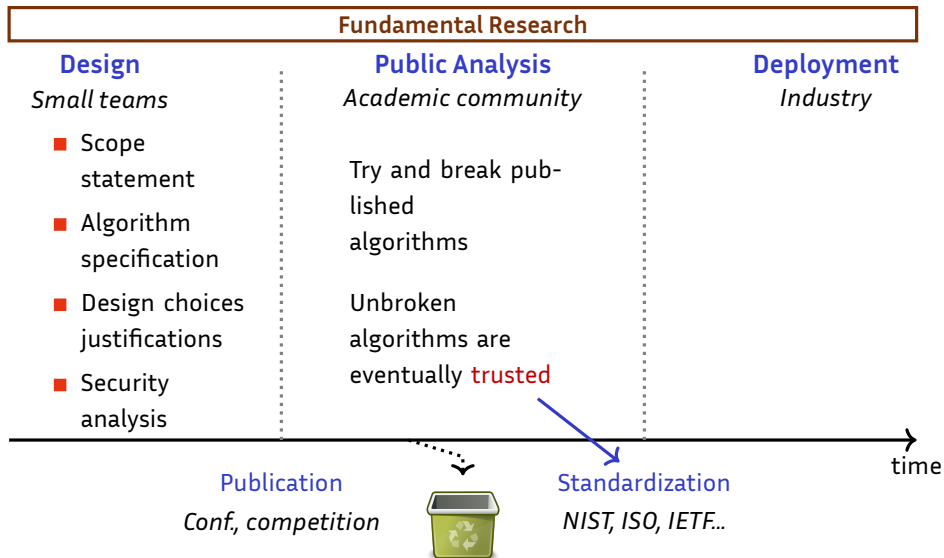

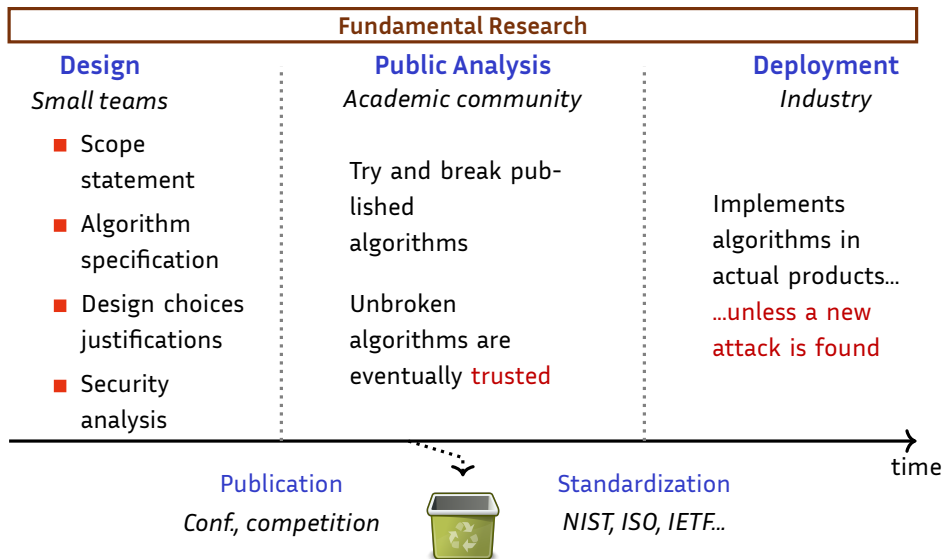

## Cryptographic Pipeline

## Cryptographic Pipeline

## Cryptographic Pipeline

## Cryptographic Pipeline

**Fundamental Research**

This process is **slow**, so we can have **trust**

## Take Away

- 1 The adoption of new hash functions will depend on how much we **trust** them, and thus on **their security arguments**
- 2 These security arguments must be based on **fundamental research**

## Plan of this Section

{arroy, crec, tyti}@dtu.dk

<sup>3</sup> IAIK, Graz University of Technology, Austria  
{christian.rechberger, lorenzo.grassi}@iaik.tugraz.at

Published at ASIACRYPT'16;

<https://eprint.iacr.org/2016/492.pdf>

- Base field:  $\mathbb{F}_q$ , where e.g.  $q = 2^{129}$
- Round function:

$$F_i \begin{cases} \mathbb{F}_q & \rightarrow \mathbb{F}_q \\ x & \mapsto (x + c_i)^3 \end{cases}$$

where the *round constants*  $c_i$  have been generated randomly.

- Number of rounds:  $\ell \approx 90$

## gMiMC

- Base field:  $\mathbb{F}_q$ , where  $q = 2^n$  or  $q = p \geq 2^n, n \geq 64$

- Round function: see left

- Number of rounds:  $\ell > 170$

Published at ESORICS'19;  
Albrecht, Perrin, Ramacher, Rechberger, Rotaru, Roy, Schofnegger

<https://eprint.iacr.org/2019/397.pdf>

## Rescue

- Base field:  $\mathbb{F}_q$ , where  $q = p \geq 2^n$ ,  $n \geq 64$
- Round function: see left;  $\alpha = 3$  and  $M$  is a linear permutation of  $\mathbb{F}_q^t$ .
- Number of rounds:  $\ell \approx 10$

Published at ToSC'20(3);  
 Aly, Ashur, Ben-Sasson, Dhooghe, Szepieniec

<https://tosc.iacr.org/index.php/ToSC/article/view/8695/8287>

**Verification:**  $P_i(x_i) == Q_i(x_{i+1})$ , where  $P_i$  is a half round,  
 and  $Q_i$  is the **inverse** of the other half!

# Poseidon

Published at USENIX'21;  
 Grassi, Khovratovich, Rechberger, Roy, Schafneger  
<https://eprint.iacr.org/2019/458.pdf>

- Base field:  $\mathbb{F}_q$ , where  $q = p \geq 2^n, n \geq 64$
- Round function:  $S(x) = x^3$ ,  $ARC$  add a round constant, and  $M$  is a linear permutation of  $\mathbb{F}_q^t$ .
- Number of rounds:  $\ell = R_f + R_P \approx 50$

## Generic Attacks

Let  $H$  be a hash function with an output in  $\mathbb{F}_q^d$ .

## Generic Attacks

Let  $H$  be a hash function with an output in  $\mathbb{F}_q^d$ .

No matter how good  $H$  is...

- 1 ... it can be inverted in time  $q^d$  (on average); (brute-force)
- 2 ... we can find  $x$  and  $y$  such that  $H(x) = H(y)$  in time  $\sqrt{q^d}$  (on average). (birthday search)

**Generic attacks** (such as these) serve as the **benchmark** to assess security levels in symmetric cryptography.

## Goal

What does it *mean* to attack a hash function?

## Goal

What does it *mean* to attack a hash function?

### Practical Attack

*Actually* exhibit  $x$  and  $y$  such that  
 $H(x) = H(y)$ .

Practically broken hash functions:

- MD4
- SHA-1

## Goal

What does it *mean* to attack a hash function?

### Practical Attack

*Actually* exhibit  $x$  and  $y$  such that  $H(x) = H(y)$ .

Practically broken hash functions:

- MD4
- SHA-1

### Theoretical Result

**Aim.** Describe an algorithm capable of finding  $(x, y)$  faster than the corresponding generic attack.

**Target.** At first, we **reduce the number of rounds** in the inner primitive.

## Goal

What does it *mean* to attack a hash function?

### Practical Attack

Actually exhibit  $x$  and  $y$  such that  $H(x) = H(y)$ .

Practically broken hash functions:

- MD4
- SHA-1

### Theoretical Result

**Aim.** Describe an algorithm capable of finding  $(x, y)$  faster than the corresponding generic attack.

**Target.** At first, we **reduce the number of rounds** in the inner primitive.

**1** **practical attacks** are found after **theoretical results**

## Goal

What does it *mean* to attack a hash function?

### Practical Attack

Actually exhibit  $x$  and  $y$  such that  $H(x) = H(y)$ .

Practically broken hash functions:

- MD4
- SHA-1

### Theoretical Result

**Aim.** Describe an algorithm capable of finding  $(x, y)$  faster than the corresponding generic attack.

**Target.** At first, we **reduce the number of rounds** in the inner primitive.

- 1 **practical attacks** are found after **theoretical results**
- 2 **theoretical results** on hash functions are found after **theoretical results** on its inner primitive (e.g. the permutation for sponge functions).

## Milestone Towards the Goal

What does it *mean* to attack a **permutation**?

## Milestone Towards the Goal

What does it *mean* to attack a **permutation**?

### Does it even make sense?

The specification of a permutation is public:  
there is no **key** to protect!

- Ideally, an attacker wants to be able to control the **capacity** of the output using only the **rate** of the input.
- The security proof of the sponge relies on the permutation “behaving like a random permutation”.

## Milestone Towards the Goal

What does it *mean* to attack a **permutation**?

### Does it even make sense?

The specification of a permutation is public:  
there is no **key** to protect!

- Ideally, an attacker wants to be able to control the **capacity** of the output using only the **rate** of the input.
- The security proof of the sponge relies on the permutation “behaving like a random permutation”.

### Examples of distinguishers

**CICO.** Can you find  $(x, 0)$  such that  $P(x, 0) = (y, 0)$  (faster than a brute-force search)?

**Low Degree.** The univariate (or algebraic) degree of  $P$  is lower than expected.

**Differential.** next slide

**Others!** Linear, integral...

## Plan of this Section

- 1 What are Arithmetization-Oriented Hash Functions
- 2 How Do We Test Their Security?
  - Principles of the Cryptanalysis of Hash Functions
  - Attack Techniques
- 3 Some Cryptanalyses
- 4 Conclusion

## Differential Attacks

Differential equation

$$P(x + a) - P(x) = b$$

## Differential Attacks

### Differential equation

$$P(x + a) - P(x) = b$$

- Aim: find  $(a, b)$  such that there are many solutions  $x$ .
- In practice, we find  $(a_i, a_{i+1})$  at each round.

## Differential Attacks

### Differential equation

$$P(x + a) - P(x) = b$$

- **Aim:** find  $(a, b)$  such that there are many solutions  $x$ .
- In practice, we find  $(a_i, a_{i+1})$  at each round.
- Successfully applied to the inner block cipher of SHA-1 (in  $\{0, 1\}^*$ ), thus leading to its break...
- ... A priori less applicable in  $\mathbb{F}_q$  (or is it?  $\rightarrow$  RESCUE)

## Algebraic Attacks

### Main equation system

$$\begin{cases} x_1 &= F_0(x_0) \\ \dots & \\ x_\ell &= F_{\ell-1}(x_{\ell-1}) \end{cases}$$

## Algebraic Attacks

### Main equation system

$$\begin{cases} x_1 &= F_0(x_0) \\ \dots & \\ x_\ell &= F_{\ell-1}(x_{\ell-1}) \end{cases}$$

- If the system can be solved, then we can enforce constraints on  $x_0$  and  $x_\ell$  (e.g. CICO).

## Algebraic Attacks

### Main equation system

$$\begin{cases} x_1 &= F_0(x_0) \\ \dots & \\ x_\ell &= F_{\ell-1}(x_{\ell-1}) \end{cases}$$

- If the system can be solved, then we can enforce constraints on  $x_0$  and  $x_\ell$  (e.g. CICO).
- First, compute a Gröbner basis of the system. Then, deduce a solution in the correct field.
- Complexity is not so easy to estimate:
  - We can give bounds based on the best Gröbner basis algorithms...
  - ... but they don't take the shape of the system into account.

# Accurate Computations of the Algebraic Degree

*Joint work with Clémence Bouvier and Anne Canteaut*

## Accurate Computations of the Algebraic Degree

*Joint work with Clémence Bouvier and Anne Canteaut*

### Definition

Algebraic Degree  $\mathbb{F}_{2^n}$  can be seen as  $(\mathbb{F}_2)^n$ , so

$G : \mathbb{F}_{2^n} \rightarrow \mathbb{F}_{2^n}$  is the same as

$G' : (\mathbb{F}_2)^n \rightarrow (\mathbb{F}_2)^n$ , where

$$G'_i = \sum_{u \in (\mathbb{F}_2)^n} \alpha_u \prod_{i=0}^{n-1} x_i^{u_i}$$

The **algebraic degree** of  $G'_i$  is the maximum Hamming weight of  $u$  such that  $\alpha_u \neq 0$ .

- $\deg^a((x, y) \mapsto xy) = 2$
- $\deg^a(x \mapsto x^3) = 2$

## Accurate Computations of the Algebraic Degree

Joint work with Clémence Bouvier and Anne Canteaut

### Definition

Algebraic Degree  $\mathbb{F}_{2^n}$  can be seen as  $(\mathbb{F}_2)^n$ , so

$G : \mathbb{F}_{2^n} \rightarrow \mathbb{F}_{2^n}$  is the same as

It must be **low**, and should **decrease** with the number of rounds/steps.

→ Experimental verification for weakened variants of **Rescue**.

## Take Away

This high probability differential *may* be a consequence of some multiplicative pattern traversing both  $x \mapsto x^3$  and the linear layer.

No Frobenius automorphism implies that only simpler linear functions are available to designers, which in turn can imply strange differential behaviour!

## Plan of this Section

- 3 Observe after each round whether each word is:

Constant

Takes all possible  
values

Sums to 0

Has no pattern  
anymore

Suppose that  $q = 1 + \prod_i p_i$ .

Then, there are many small multiplicative subgroups in  $\mathbb{F}_q$ , where all these properties are well defined!

## Take Away

A basic saturation attack requires  $q$  queries to the permutation. If  $q$  is larger than the security parameter, they are infeasible.

The presence of **small multiplicative subgroups** significantly enhances **saturation attacks** by decreasing their data complexity!

## Plan of this Section

- 1 What are Arithmetization-Oriented Hash Functions
- 2 How Do We Test Their Security?
- 3 Some Cryptanalyses
- 4 Conclusion**

## Conclusion

- 1 Designing arithmetization-oriented hash functions is **difficult** because it is largely **uncharted territory**:
  - if  $q = 2^n$ , estimating the algebraic degree is hard (MiMC);
  - if  $q = p$ , multiplicative subgroups bother us (gMiMC);
  - if  $q = p$ , absence of Frobenius automorphisms  $\rightarrow$  fewer options for linear operations (RESCUE).

## Conclusion

- 1 Designing arithmetization-oriented hash functions is **difficult** because it is largely **uncharted territory**:
  - if  $q = 2^n$ , estimating the algebraic degree is hard (MiMC);
  - if  $q = p$ , multiplicative subgroups bother us (gMiMC);
  - if  $q = p$ , absence of Frobenius automorphisms  $\rightarrow$  fewer options for linear operations (RESCUE).
- 2 There are **theoretical issues** with several of the new hash functions...

## Conclusion

- 1 Designing arithmetization-oriented hash functions is **difficult** because it is largely **uncharted territory**:
  - if  $q = 2^n$ , estimating the algebraic degree is hard (MiMC);
  - if  $q = p$ , multiplicative subgroups bother us (gMiMC);
  - if  $q = p$ , absence of Frobenius automorphisms  $\rightarrow$  fewer options for linear operations (RESCUE).
- 2 There are **theoretical issues** with several of the new hash functions...
- 3 There is room for improvement!

## Conclusion

- 1 Designing arithmetization-oriented hash functions is **difficult** because it is largely **uncharted territory**:
  - if  $q = 2^n$ , estimating the algebraic degree is hard (MiMC);
  - if  $q = p$ , multiplicative subgroups bother us (gMiMC);
  - if  $q = p$ , absence of Frobenius automorphisms  $\rightarrow$  fewer options for linear operations (RESCUE).
- 2 There are **theoretical issues** with several of the new hash functions...
- 3 There is room for improvement!

*Changing the underlying mathematical structure in cryptographic primitives is a significant change that requires substantial care.*

## Conclusion
